The simplest practical case of mobile radio channel is the one affected by additive white Gaussian noise (AWGN).

- Complex base-band notation is understood.
- This channel applies when the mobile and the surrounding scenario are not in motion.
- The received signal is perturbed by additive noise and by a fixed path loss that includes shadowing.

A key parameter to evaluate the performance of a TLC system is the Signal to Noise Ratio (SNR).

- It is the ratio between the signal and the noise powers and is given by:

$$\gamma = \frac{E(A^2 u^2(t))}{2P_n} = \frac{A^2}{2\sigma_n^2} \quad (1)$$

- where σ_n^2 is the variance of the zero-mean Gaussian processes that characterize the real and imaginary parts of the complex base-band noise components.
- a unit variance is assumed for the modulator output.

fading

When dealing with the performance of a digital TLC systems it is more convenient to deal with the Bit Error Rate (BER).

- In case of a symbol with a finite duration T , whose energy is E_s (it consists of m bits with energy E_b), the SNR can be expressed as follows:

$$\gamma \propto \frac{E_s}{N_o} = \frac{mE_b}{N_o} \quad (2)$$

BER for a digital modulation scheme

It can be shown that the BER is given by:

$$BER = Q \left(\sqrt{\frac{A^2 d^2}{2N_o}} \right) \quad (3)$$

with d being the Euclidean distance between the TX symbols.

Mobile radio performance - in general - is worse than the AWGN case since propagation is affected by fast fading, i.e.; a multiplicative, time-variant process.

Fast fading

Fast fading indicates the fluctuations in the received signal as a result of multipath components. Several replicas of the signal arrive at the receiver through different propagation paths, adding constructively and destructively.

- Fast fading can be further divided in:
 - Flat or Narrowband fast fading.
 - Frequency selective or Wideband fast fading.

fading

Narrowband fading channel

Multipath fading due to small path length differences between rays coming from scatterers in the near vicinity of the mobile. Hence, although significant phase differences are experienced, the rays all arrive at essentially the same time, so all frequencies within a wide bandwidth are affected in the same way.

Wideband fading channel

Strong scatterers are present well-off of the great circle path between the base and mobile. Time difference between rays may be large compared to the basic unit of information transmitted on the channel (usually a symbol or a bit), the signal will then experience significant distortion, which varies across the channel bandwidth.

Reverberating chamber

Wideband fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband fading

It affects all the frequencies of the signal equally. This means that it can be modeled as a single multiplicative process.

$$y(t) = A\alpha(t)u(t) + n(t) \quad (4)$$

where $\alpha(\cdot)$ is the complex fading coefficient and baseband notation is used, i.e.; $u(\cdot)$ and $n(\cdot)$ are phasors.

Wideband
fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband
fading

Fading varies with time; hence, SNR also will vary with time.

This implies, that, despite the AWGN case, the instantaneous $\gamma(t)$ and the mean Γ SNR must be considered.

$$\gamma(t) = \frac{A^2 |\alpha(t)|^2 E(|u(t)|^2)}{2P_n} = \frac{A^2 |\alpha(t)|^2}{2P_n} \quad (5)$$

$$\Gamma = E(\gamma(t)) \quad (6)$$

The performance of a fading channel is fully characterized by:

- the mean SNR;
- variations of the instantaneous SNR around the mean SNR.

Fading, i.e.; multipath propagation

Fading means that, due to the presence of objects, several waves reach RX by different routes: multipath propagation. Two scenarios must be distinguished:

NLOS

LOS

Wideband
fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband
fading

Multipath means that the propagation medium contains several distinguishable “paths” that connect TX and RX. Hence, some fraction of the total energy unavoidably arrives over each path. Two main scenarios must be distinguished:

LOS

A single stronger direct path that connects TX and RX exists, along with multipath links due to local scatterers.

NLOS

The direct link between TX and RX is blocked. Waves reaching the receiver call for a uniformly distributed phase value. This means that all the multi-paths are equally probable.

The Rice distribution is often expressed in terms of the Rice factor k .

Rice factor

$$k = \frac{\text{Power of the LOS part}}{\text{Power of the multipath part}} = \frac{s^2}{2\sigma^2} \quad (11)$$

- Hence, the Rice distribution can be written as:

$$p_R(r) = \frac{r}{\sigma^2} e^{\left(\frac{-r^2}{2\sigma^2}\right)} e^{-k} I_0\left(\frac{\sqrt{2}rk}{\sigma}\right) \quad (12)$$

fading

The specific shape of the signal's spectrum can be explained in terms of Doppler spreading.

- A mobile moves at a velocity v_m in straight line.
- The mobile direction makes an angle θ_1 with the incoming em wave.

The Doppler effect

It results in a shift of the frequency of the incoming wave by a factor that is proportional to the component of the mobile speed along with the em wave direction.

The frequency increases (decreases) when the mobile moves towards (away from) the source.

The Doppler shift

fading

The Doppler shift

It is associated with the rate at which the mobile crosses wavefronts of the incoming em wave.

- The Doppler shift f_d is given by:

$$f_d = f_m \cos \theta \quad \text{with } f_m = f_c \frac{v}{c} \quad (13)$$

- f_m is the maximum Doppler shift and it is associated to $\theta = 0$.
- The Doppler shift f_d associated to the em wave can have apparent frequency in the range:

$$f_c - f_m \leq f \leq f_c + f_m \quad (14)$$

The Doppler bandwidth

- In case of multipath, waves arrive with several directions.

- Each wave has its own Doppler shift.
- The bandwidth of the received signal is therefore spread wrt the transmitted one: Doppler spread.

The overall spectral width associated to the received signal is termed as Doppler bandwidth.

The Doppler spectrum

The Doppler spectrum affects significantly second-order fading statistics.

- To model the Doppler spectrum, assumptions on the arriving angle of the multipath signals must be done.
- To obtain a reference model, one can assume arriving angles being uniformly distributed within $[-\pi, \pi]$. Hence, $p(\theta) \propto U(-\pi, \pi)$.
- If the mobile antenna is pointing in the direction θ , with a gain $G(\theta)$, the mean power arriving from an elementary angle $d\theta$ is given by:

$$P(\theta) = G(\theta)p(\theta)d\theta \quad (15)$$

The classical Doppler spectrum

Wideband fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband fading

- The power spectrum of the received signal $S(f)$ is simply given by:

$$P(f) = S(f)df \quad (16)$$

- Hence, noting that two angles $\pm\theta$ call for the same Doppler shift:

$$|S(f)| = \frac{G(\theta)p(\theta) + G(-\theta)p(-\theta)}{|df/d\theta|} \quad (17)$$

- Since, $|df/d\theta| = f_m |1 - \sin\theta|$ and assuming $G(\theta) = 1.5$:

$$|S(f)| = \frac{1.5/2\pi + 1.5/2\pi}{f_m |1 - \sin\theta|} = \frac{1.5}{\pi f_m \sqrt{1 - (f/f_m)^2}} \quad (18)$$

- In the last step, $\sin\theta = \sqrt{1 - \cos^2\theta} = \sqrt{1 - (f/f_m)^2}$

The effects of the Doppler spread can be analyzed in the time domain using the autocorrelation function that deals with the correlation of a signal with its delayed version.

$$\rho(\tau) = \frac{E[\alpha(\tau)\alpha^*(t + \tau)]}{E[|\alpha|^2]} \quad (19)$$

- When a classical Doppler spectrum with Rayleigh fading is assumed, the autocorrelation function becomes:

$$\rho(\tau) = J_0(2\pi f_m \tau) \quad (20)$$

- with $J_0(\cdot)$ being the Bessel function of the first kind and zero order.

The baseband received signal is assumed to be made of N waves coming from the N paths.

$$\begin{aligned}y(t) &= y_c(t) + jy_s(t) \\y_c(t) &= \frac{1}{\sqrt{N}} \sum_{n=1}^N \cos(\omega_d t \cos \alpha_n + \phi_n) \\y_s(t) &= \frac{1}{\sqrt{N}} \sum_{n=1}^N \sin(\omega_d t \cos \alpha_n + \phi_n)\end{aligned}\quad (23)$$

- ω_d is the maximum radian Doppler frequency;
- $\alpha_n = \frac{2\pi n + \theta_n}{N}$ is the arriving angle;
- ϕ_n and θ_n are statistically independent and uniformly distributed over $[-\pi, \pi)$ for all n .

The signal that arrives at the receiver consists of multiple beams.

- Each beam consists of several waves that, due to the scattering properties of the obstacles, may be affected by narrowband fading.
- If the delay of the beams is comparable or even larger than the symbol duration, wideband fading occurs.

- The signal received by the mobile terminal consists of the sum of the waves (echoes) resulting from each scatterer.
- Each wave will call for a phase θ and an amplitude a that are related to the electrical and geometrical properties of the scatterer.
- The time delay that characterizes each wave is given by eq.(24).

The signal r received by the mobile is given by:

$$r = a_1 e^{j(\omega\tau_1 + \theta_1)} + a_2 e^{j(\omega\tau_2 + \theta_2)} + \dots \quad (25)$$

In the narrowband channel, the time delays are approximately the same.

$$r = e^{j\omega\tau} \left(a_1 e^{j\theta_1} + a_2 e^{j\theta_2} + \dots \right). \quad (26)$$

- The amplitude does not depend on the carrier frequency.
- The channel can be considered as a single multiplicative process since all the frequencies of the received signal are affected in the same way by the channel.
- No signal distortion occurs.

Frequency domain

Overcome wideband
fading

Let's suppose to transmit a signal whose bandwidth is 1MHz

- If $\Delta\tau = 0.1\mu s$, the transfer function cancels at multiple of 10MHz. Hence, the TX signal would experience a constant attenuation and the channel is a narrowband one.
- If $\Delta\tau = 1\mu s$, the transfer function cancels at multiple of 1MHz. Hence, the channel amplitudes vary significantly across the signal bandwidth and it must be considered wideband.

Overcome wideband fading

The energy of the TX symbol is spread in time. Hence, the symbol reaches the receiver with a delay that consists of a constant transmission delay plus a delay spreading

The symbol is still arriving at the receiver when the energy associated to the next symbol starts arriving: ISI.

The ISI makes the BER reaches a floor (aka “error floor”) at larger SNR.

Despite the case of narrowband fading where BER decreases without any limit, in this case ISI dominates at higher signal levels flattening the BER wrt SNR.

Wideband fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband fading

The effects of scatterers at discrete delays ranges are concentrated in individual taps each representing single beam whose amplitude varies in time according to the narrowband fading statistics.

Wideband channel

Wideband channel is therefore a combination of several paths subjected to narrowband fading, combined together with appropriate delays

Input delay spread function

- The beams are assumed to be uncorrelated from each other. This is justified by the fact that they arise from physically distinct scatterers that are separated by many wavelengths.
- Wideband channels is characterized by a time-variant impulse response function, aka **input delay spread function**:

Input delay spread function

$$y(t) = u(t) * h(t, \tau) = \int_{-\infty}^{+\infty} h(t, \tau) u(t - \tau) d\tau \quad (28)$$

Few synthetic parameters may be used to characterize PDP

- Total excess delay: It describes the spreading of the symbol when transmitted through the channel. It is given by the difference between the delays of the first and the last arrived beam.
- Mean delay

$$\tau_o = \frac{1}{P_T} \sum_{i=1}^N P_i \tau_i \quad P_T = \sum_{i=1}^N P_i \quad (30)$$

- RMS delay spread τ_{rms} . It described the spreading of the delay with respect to the mean delay.

$$\tau_{RMS} = \sqrt{\frac{1}{P_T} \sum_{i=1}^N P_i \tau_i^2 - \tau_o^2} \quad (31)$$

| Environment | Approximate RMS delay spread [μ s] |
|----------------------|---|
| Indoor cells | 0.01-0.05 |
| Mobile satellite | 0.04-0.05 |
| Open area | <0.2 |
| Suburban macrocell | <1 |
| Urban macrocell | 1-3 |
| Hilly area macrocell | 3-10 |

These values indicate that, for instance, indoor cells may admit (nominal) data rates larger than hilly area macrocells. Equalization techniques must be applied to improve data rates in hilly areas reducing ISI.

Time-variant transfer function (TVT)

The channel may be analyzed in the frequency domain where it is fully characterized by its TVT. Hence the channel may be considered as a filter with a time-variant frequency response.

TVT

$$T(f, t) = F[h(t, \tau)] = \int_{-\infty}^{+\infty} h(t, \tau) e^{-j2\pi f \tau} d\tau \quad (32)$$

- The spectrum of the output signal at the time t is given by:

$$Y(f, t) = U(f)T(f, t) \quad (33)$$

Wideband
fading

Introduction

Effects

Channel model

Frequency domain

Overcome wideband
fading

- In practical cases, TVT is unknown a priori. The channel can be hence characterized in terms of the correlation between frequency components of the output spectrum separated by a given shift.
- The correlation between two components of the TVT function separated by Δf and Δt is denoted by $\rho(\Delta f, \Delta t)$.

Coherence bandwidth B_c

It is the Δf that makes $\rho(\Delta f, \Delta t)$, evaluated at $\Delta t = 0$, equals 0.5.

A wideband channel is such that the signal bandwidth is larger than B_c or, equivalently, the symbol duration is shorter than τ_{rms}

$$B_c \propto \frac{1}{\tau_{rms}} \quad (34)$$

Overcome wideband fading

- **Directional antennas:** to reduce the energy transmitted towards scatterers resulting in far-out echoes.
- **Small cells:** they allow a reduced maximum differential delay.
- **Diversity:** It allows reducing the level of deep fades therefore reducing the SNR for a given BER and, hence, the error floor is reduced
- **Equalizers:** It consists of applying an adaptive filter to flatten the channel frequency response or by making constructive use of the energy in the delayed taps.
- **Data rate:** By transmitting the required data simultaneously on a large number of carriers, each with a narrow bandwidth, the data throughput can be maintained (OFDM) and wideband fading is attenuated.
