Example of controller design

 \checkmark Let us consider a closed loop system in the form

where

$$H(s) = \frac{0.1}{1 + 0.2s}$$

$$G(s) = \frac{2(1+s)}{(1+10s)(1+s\tau)}$$

with $\tau \in \begin{bmatrix} 0 & 0.04 \end{bmatrix}$

Let us consider the following requirements:

- 1. $e_{\infty r} \leq 5\%$ for a reference signal $r(t) = r_0 t \cdot 1(t)$
- 2. $e_{\infty r} \leq 0.05$ for multi-frequency disturbs in the range [0.01 0.5] rad/s
- 3. $e_{\infty r} \leq 0.1$ for multi-frequency reference signal in the range $\begin{bmatrix} 0 & 1 \end{bmatrix}$ rad/s
- 4. Attenuation $\geq 20_{db}$ for multi-frequency noise in the range [50 100] rad/s
- 5. Phase margin $\varphi_m > 30^\circ$

Example of controller design

▲ Making use of the block diagrams algebra, the closed loop scheme can be equivalently written in the form

where

 $E(s) = H^{-1}(s)\tilde{E}(s)$

1. $e_{\infty r} \leq 5\%$ for a reference signal $r(t) = r_0 t \cdot \mathbf{1}(t)$

- ▲ Steady-state requirement for polynomial reference signal of order 1.
- A The subscript r in $e_{\infty r}$ indicates that the requirement considers the relative steadystate error (independent on the amplitude of the reference signal r_0)
- A To assure a finite steady state error for a polynomial signal of order 1 it is necessary that F(s) is of type 1, that is F(s) should have a pole in the origin.
- A Taking into account that the plant transfer function G(s) doesn't contain poles in the origin, the steady-state part of the controller is

$$K'(s) = \frac{k_0}{s}$$

where k_0 is chosen so that

$$\lim_{s \to 0} s \frac{1}{1 + K'(s)G(s)H(s)} \frac{1}{s^2} < 0.05 \quad \to \quad k_0 \ge 100$$

2. $e_{\infty r} \leq 0.05$ for multi-frequency disturbs in the range $\begin{bmatrix} 0.01 & 0.5 \end{bmatrix}$ rad/s

- ▲ Steady-state requirement for multi-frequency disturbs
- \checkmark It implies that

$$|S(s)| = \left| \frac{1}{1 + K'(s)G(s)H(s)} \right| \le 0.05 \quad \rightarrow \left| \frac{1}{F(s)} \right| \le 0.05 \quad \rightarrow |F(s)|_{db} \ge 26_{db}$$

$$26_{db}$$

$$0.00$$

$$0.5 \qquad \omega$$

3. $e_{\infty r} \leq 0.1$ for multi-frequency reference signal in the range $\begin{bmatrix} 0 & 1 \end{bmatrix}$ rad/s

- ▲ Steady-state requirement for multi-frequency reference
- \checkmark It implies that

$$|S(s)| = \left| \frac{1}{1 + F(s)} \right| \le 0.1 \quad \rightarrow \left| \frac{1}{F(s)} \right| \le 0.1 \quad \rightarrow \quad |F(s)|_{db} \ge 20_{db}$$

4. Attenuation $\geq 20_{db}$ for multi-frequency noise in the range [50 100] rad/s

▲ Steady-state requirement for multi-frequency noise

▲ -It implies that
$$|T(s)| = \left| \frac{F(s)}{1+F(s)} \right|_{db} \le -20_{db} \rightarrow |F(s)|_{db} \le -20_{db}$$

5. $\varphi_m > 30^\circ$

- ▲ The transient performance considers only the overshoot of the step response
- A The crossing frequency of F(s) is imposed by the multi-frequency requirements

▲ However, looking at the forbidden zones, it is reasonable to place the crossing frequency $ω_c \in [10 \ 20]$ rad/s

- ▲ Design the controller K(s) so that the open loop function F(s) = K(s)G(s) satisfies the previous requirements
- \checkmark The controller will be in the form

$$K(s) = K'(s) \cdot K''(s)$$

where

K'(s) have been designed according to the steady-state requirements concerning polynomial reference and/or disturbs

$$K'(s)=\frac{100}{s}$$

K''(s) have to be designed according to the steady-state multi-frequency requirements and the transient requirements

 \checkmark In order to design K''(s), let us consider the uncertain transfer function

$$F'(s) = K'(s)H(s)G(s) = \frac{20(1+s)}{s(1+10s)(1+s\tau)(1+0.2s)}$$

with $\tau \in [0 \quad 0.04]$.

A The transfer function F'(s) contains an uncertain pole whose breaking point moves from 25 rad/s to $+\infty$.

- ▲ Taking into account that the desired crossing frequency $ω_c \in [10 \ 20]$ rad/s, the effects of the uncertain pole on F(s) can be summarized as:
 - ▲ It doesn't modify the crossing frequency ω_c for any values of τ
 - ▲ It causes a phase leg in $\omega = \omega_c$ and hence it reduces the phase margin. The maximum phase lag is due to $\tau = 0.04$.
 - ▲ It attenuates the magnitude in the interval [50 100] rad/s when $\tau \in [0.02 \ 0.04]$ and hence it makes easier to satisfy the constraint on the multi-frequency noise
- ▲ In order to design a robust controller w.r.t. the variation of the uncertain pole, we will assume:
 - ▲ *τ* = 0.04 when we evaluate the phase margin
 - ▲ *τ* = 0 when we evaluate the magnitude Bode plot of *F*(*s*)

A Magnitude Bode plot of $F'(s) = \frac{20(1+s)}{s(1+10s)(1+0.2s)}$

▲ In order to verify the multi-frequency requirements, we need:

- ▲ Amplification $\ge 8_{db}$ in ω = 0.5 rad/s
- ▲ Amplification $\geq 12_{db}$ in ω = 1 rad/s

With a degree of freedom related to a possible amplification $\leq 28_{db}$ in $\omega = 50$ rad/s

Assuming a crossing frequency $\omega_c \cong 10 \text{ rad/s}$, the current phase margin is $\varphi_m = 180 + \varphi_c = 180 + (-90 - 90 - 60 - 30 + 90) = 0$ \swarrow Pole in the Pole in Pole in Uncer. Zero in origin -0.1 -5 pole in -1 -25

A The controller K''(s) can be easily defined by

$$K''(s) = \frac{(1+10s)}{(1+s)}$$

- \checkmark In this way we have
 - * 13_{db} magnitude amplification in $\omega = 0.5$ rad/s
 - * 17_{db} magnitude amplification in $\omega = 1$ rad/s
 - ★ Crossing frequency $\omega_c \cong 10 \text{ rad/s}$
 - * NO phase anticipation in $\omega = 10 \text{ rad/s} \quad (\varphi_m \cong 0)$
 - * 20_{db} magnitude amplification in $\omega = 50$ rad/s
- ▲ Finally, we can add a zero with a breaking frequency ω = 20 rad/s to assume a phase margin $φ_m \cong 30$ without intersecting the noise forbidden zone.

 \checkmark The controller is in the form

$$K(s) = K'(s)K''(s) = \frac{100(1+10s)(1+0.05s)}{s(1+s)}$$
