## Hebbian Learning and Component Analysis

Angelo Ciaramella

# Hebbian learning and NNs

---

- NNs based on the Hebb's rule
  - Oja's rule
    - computer scientist **Erkki Oja**
    - Unsupervised learning
    - Symmetric Oja Space
  - Sanger's rule
    - scientist **Terence D. Sanger**
    - Unsupervised learning
    - Selective Principal Components
  - Generates an algorithm for
    - Principal Component Analysis (PCA)
    - non-linear PCA
    - Independent Component Analysis (ICA)

# Principal Component Analysis

- Principal Component Analysis (PCA) is a statistical technique
  - Dimensionality reduction
  - Lossy data compression
  - Feature extraction
  - Data visualization
- It is also known as the *Karhunen-Loeve* transform
- PCA can be defined as the principal subspace such that the variance of the projected data is maximized

# Second-Order methods

---

- The **second-order methods** are the most popular methods to find a **linear transformation**
- This methods find the representation using only the information contained in the **covariance matrix** of the data vector  $\mathbf{x}$
- **PCA** is widely used in signal processing, statistics, and neural computing

# Principal Components

In a linear projection down to one dimension, the optimum choice of projection, in the sense of minimizing the sum-of-squares error, is obtained first subtracting off the mean of the data set, and then projecting onto the first eigenvector  $\mathbf{u}_1$  of the covariance matrix.

# Projection error minimization

- We introduce a complete orthonormal set of  $D$ -dimensional basis vectors ( $i=1, \dots, D$ )

$$\mathbf{u}_i^T \mathbf{u}_j = \delta_{ij}$$

- Because this basis is complete, each data point can be represented by a linear combination of the basis vectors

$$\mathbf{x}_n = \sum_{i=1}^D \alpha_{ni} \mathbf{u}_i$$

# Projection error minimization

- We can write also that

$$\mathbf{x}_n = \sum_{i=1}^D (\mathbf{x}_n^T \mathbf{u}_i) \mathbf{u}_i \quad \leftarrow \quad \alpha_{nj} = \mathbf{x}_n^T \mathbf{u}_j$$

- Our goal is to **approximate** this data point using a representation involving a restricted number  $M < D$  of variables corresponding to a **projection** onto a lower-dimensional subspace

$$\tilde{\mathbf{x}}_n = \sum_{i=1}^M z_{ni} \mathbf{u}_i + \sum_{i=M+1}^D b_i \mathbf{u}_i$$

# Projection error minimization

- As our distortion measure we shall use the **squared distance** between the original point and its approximation averaged over the data set so that our goal is to minimize

$$J = \frac{1}{N} \sum_{n=1}^N \|\mathbf{x}_n - \tilde{\mathbf{x}}_n\|^2$$

- The **general solution** is obtained by choosing the basis to be eigenvectors of the covariance matrix given by

$$\mathbf{S}\mathbf{u}_i = \lambda_i \mathbf{u}_i$$

# Projection error minimization

- The corresponding value of the **distortion measure** is then given by

$$J = \sum_{i=M+1}^D \lambda_i$$

- We **minimize** this error selecting the **eigenvectors** defining the principal subspace are those corresponding to the  $M$  largest eigenvalues

# Complex distributions

A linear dimensionality reduce technique, such as PCA, is unable to detect the lower dimensionality. In this case PCA gives two eigenvectors with equal eigenvalues. The data can be described by a single eigenvalue

Addition of a small level of noise to data having an intrinsic dimensionality of 1 can increase its intrinsic dimensionality to 2. The data can be represented to a good approximation by a single variable  $\eta$  and can be regarded as having an intrinsic dimensionality of 1.

# Unsupervised Neural Networks

---

- Typically **Hebbian** type **learning** rules are used
- There are two type of NN able to extract the Principal Components:
  - **Symmetric** (Oja, 1989)
  - **Hierarchical** (Sanger, 1989)

# Information and Hebbian Learning

## ■ Information extraction

Hebbian learning - self-amplification

$$\Delta w_i = \eta y x_i$$

the net learns to respond the patterns that present the most frequent samples

# Principal Component

- Weights can grow to infinity
  - Solution – normalization (no - local)

$$w_i = \frac{w_i}{\|\mathbf{w}\|}$$

- Competition mechanism for a stable solution
  - weights in the direction of maximum variance of the distribution
  - Maximization of the variance on the output
  - weights in the direction of the eigenvector corresponding to the maximum eigenvalue of the correlation matrix

$$C = \langle \mathbf{x}\mathbf{x}^T \rangle_{\mu}$$

# Oja's rule

## ■ Idea

Information feedback

# Oja's rule

---

- Normalization is not local
- Oja's rule

$$\Delta w_j = \eta (x_j - w_j y)$$

Forgetting factor

- More outputs

$$\Delta w_{ij} = \eta y_i \left( x_j - \sum_{k=1}^n w_{kj} y_k \right)$$

# Symmetric NN

Single layer Neural Network

$$E[y^2] = E[(\mathbf{w}^T \mathbf{x})^2]$$

Symmetric PCA NN

Objective function

# Sanger's rule

---

- Sanger's learning rule

$$\Delta w_{ij} = \eta y_i \left( x_j - \sum_{k=1}^i w_{kj} y_k \right)$$

# Hierarchical NN

Single layer Neural Network

Hierarchical PCA NN

# Oja's rule vs. Sanger's rule

---

- Oja's rule
  - Symmetric Space
  - Principal Components without a specific order
- Sanger's rule
  - Hierarchical space
  - Principal Components without a specific order
    - weights of the first output neuron corresponding to the first component, weights of the second neuron to the second residual component, and so on

# Mixing matrix

# Non-linear objective function

Maximization

$$\mathbf{x} \xrightarrow{\mathbf{w} \text{ (weights)}} E \{ f(\mathbf{w}^T \mathbf{x}) \}$$

L-dimensional vector

where  $E$  is the expectation with respect to the (unknown) density of  $\mathbf{x}$  and  $f(\cdot)$  is a continue function (e.g.  $\ln \cosh(\cdot)$ )

Taylor series

$$\ln \cosh(y) = \frac{1}{2} y^2 - \frac{1}{12} y^4 + \frac{1}{45} y^6 + O(y^8)$$

$$E \{ \ln \cosh(y) \} = \frac{1}{2} E \{ (w^T x)^2 \} - \frac{1}{12} E \{ (w^T x)^4 \} + \frac{1}{45} E \{ (w^T x)^6 \} + E \{ O((w^T x)^2) \}$$

$$C = I \quad \text{and} \quad \frac{1}{2} E \{ (w^T x)^2 \} = \frac{1}{2}$$

$$-\frac{1}{12} E \{ (w^T x)^4 \}$$

That is dominating, and the kurtosis is optimized

# Robust and non-linear PCA

## Robust PCA

$$J_1(\mathbf{w}) = E[f(\mathbf{x}^T \mathbf{w})] + \sum_{j=1}^{I(i)} \lambda_{ij} [\mathbf{w}_i^T \mathbf{w}_j - \delta_{ij}]$$

$$\mathbf{w}(k+1) = \mathbf{w}(k) + \mu_k g(\mathbf{y}_i(k)) e_i(k)$$

## Standard PCA

$$E[\mathbf{y}^2] = E[(\mathbf{w}^T \mathbf{x})^2]$$

$$J_2(e_i) = 1^T E[f(\mathbf{x} - \hat{\mathbf{x}}_i)]$$

$$\mathbf{w}(k+1) = \mathbf{w}(k) + \mu_k \left( \mathbf{w}_i(k)^T g(e_i(k)) \mathbf{x}_k + \mathbf{x}_k^T \mathbf{w}_i(k) g(e_k(i)) \right)$$

## Nonlinear PCA

$$E[|b_i(k)|^2]$$

$$b_i(k) = \mathbf{x}_k - \sum_{j=1}^{I(i)} g(\mathbf{y}_j(k)) \mathbf{w}_j(k)$$

$$\mathbf{w}_i(k+1) = \mathbf{w}_i(k) + \mu g(\mathbf{y}_i(k)) b_i(k)$$

Descent gradient algorithm

$$e(k) = \mathbf{x}_k - \sum_{j=1}^{I(i)} \mathbf{y}_j(k) \mathbf{w}_j(k)$$
